#### **Introduzione.**

Il “*Progetto Integrato Tegnùe*” nacque spontaneamente dall’esigenza di alcuni ricercatori, appartenenti a Istituzioni diverse (CNR-ISMAR di Venezia, Università di Padova - Dipartimento di Biologia, ISPRA di Chioggia), di sviluppare uno studio integrato sull’ecologia degli affioramenti rocciosi presenti nel tratto di costa antistante il litorale di Chioggia, denominati “*tegnùe*”, alcune delle quali sono state elette da pochi anni a Zone a Tutela Biologica (ZTB). Recenti studi hanno infatti evidenziato come la mancanza delle necessarie informazioni sulle diverse componenti biotiche ed abiotiche di un’area protetta, sulle relazioni che intercorrono fra essi e sugli scambi che avvengono con le aree vicine, possa limitare, o addirittura inficiare, gli effetti positivi delle norme di protezione.

In sintesi, questo Progetto si prefiggeva di raggiungere i seguenti obiettivi: i) caratterizzare da un punto di vista biotico e abiotico questi ecosistemi, scarsamente indagati; ii) valutare i principali processi biogeochimici che li caratterizzano; iii) monitorare nel tempo l’efficacia delle norme di protezione sui popolamenti; iv) verificare il possibile ruolo di queste aree protette per la produzione di larve di pesci ed invertebrati verso le aree limitrofe; v) costituire un data-base ambientale utile a studi sui cambiamenti climatici.

A questo scopo, nel febbraio 2006 si diede inizio ad un *survey* preliminare, di durata triennale, volto alla raccolta di dati sull’idrologia, la correntometria, la chimica ed il plancton di alcune tegnùe nord-adriatiche. Qui vengono riportati i risultati relativi ai parametri idrologici ed al campo di corrente, rappresentati mediante tabelle, grafici e mappe tematiche.

#### **Materiali e metodi.**

La fase sperimentale è stata condotta con i mezzi nautici messi a disposizione dal CNR-ISMAR di Venezia (m/b “*Boreana*”) e dall’Associazione “*Tegnùe di Chioggia Onlus*” (m/b “*Falco II*”).

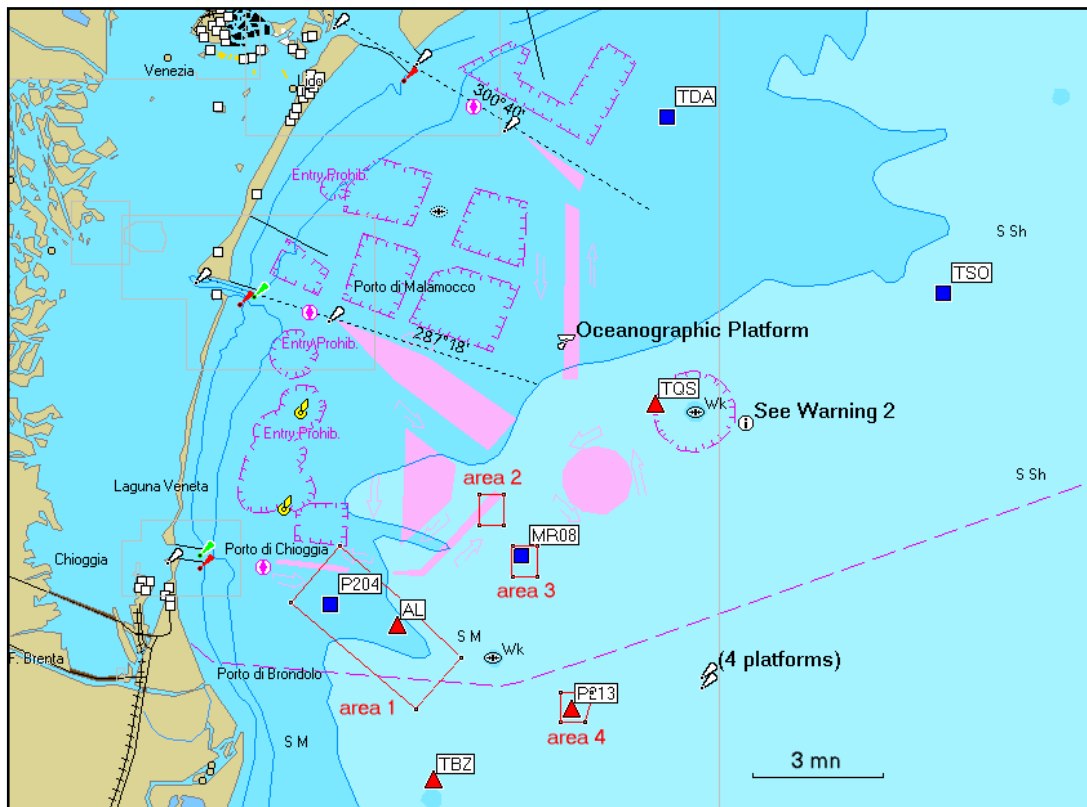

Sono state considerate 8 tegnùe, 4 poste entro le ZTB, 4 poste al di fuori, come controllo.

<b><i>tegnùe</i></b>	<b><i>lat N (WGS84)</i></b>	<b><i>lon E (WGS84)</i></b>	<b><i>distanza dalla costa (mn)</i></b>	<b><i>posizione</i></b>
TSO - Sorse	45° 19,931'	12° 43,259'	10,5	controllo
TDA - D'Ancona	45° 24,040'	12° 34,150'	3,9	controllo
TQS - Quintino Sella	45° 17,354'	12° 33,794'	10,4	controllo
MR08 - boa sub Chioggia	45° 13,825'	12° 29,365'	8,0	area 3
P204 - boa sub Mestre	45° 12,665'	12° 23,038'	3,5	area 1
AL - boa sub Adria	45° 12,189'	12° 25,275'	4,6	area 1
P213 - boa sub Padova	45° 10,264'	12° 30,999'	7,7	area 4
TBZ - Benzina	45° 08,621'	12° 26,470'	4,6	controllo

L'approccio sperimentale è stato condotto con una duplice strategia, volta a:

1. *studiare la variabilità stagionale dell'idrologia e del plancton*: lungo la colonna d'acqua delle 8 tegnùe sono state effettuate misure idrologiche a cadenza mensile mediante sonda multiparametrica (▲), mentre, su un numero ridotto di stazioni (TDA, TSO, MR08, P204), sono stati aggiunti dei campionamenti stagionali a quote fisse per lo studio delle variabili chimiche e del plancton (■);
2. *stimarne la variabilità a breve scala temporale*: per esaminare le variazioni dell'idrologia e della velocità di corrente a breve scala temporale (ore), sono state condotte misurazioni in continuo mediante strumentazione autoregistrante posta al fondo delle tegnùe P204, in area 1 (a cura dell'ISPRA di Chioggia), ed MR08, in area 3 (a cura del CNR-ISMAR di Venezia). In questo report vengono valutati i risultati ottenuti sulla sola tegnùa MR08.

Stazioni esaminate: ▲ = idrologia; ■ = idrologia, chimica e biologia.

Di seguito, vengono descritte le metodologie utilizzate durante la fase sperimentale.

### *1. Studio della variabilità stagionale dell'idrologia e del plancton.*

La trasparenza è stata valutata mediante il disco di Secchi. I profili verticali sono stati eseguiti mediante sonda multiparametrica Idronaut<sup>®</sup> 316 interfacciata con personal computer, relativamente a temperatura, salinità, ossigeno disciolto, pH, torbidità e clorofilla *a*. Prima di ogni campagna di misure, lo strumento veniva calibrato seguendo le indicazioni della ditta costruttrice. I dati acquisiti sono stati filtrati e mediati al dbar mediante software sviluppato dal CNR-ISMAR. I valori di salinità sono stati corretti per la deriva strumentale dopo calibrazione della sonda in vasca termostata contro salinometro da laboratorio Guildline<sup>®</sup> Autosal4, mentre le misure di pH sono state calibrate contro standard NBS<sup>®</sup> a pH 7,00 e 9,00.

I campioni discreti, raccolti mediante bottiglie Niskin alle quote di 1, 7 ed 1 m dal fondo, riguardavano l'ossigeno disciolto, i nutrienti e la clorofilla *a*. L'ossigeno disciolto è stato fissato a bordo e titolato in laboratorio sec. Winkler (Strickland e Parsons, 1968); i nutrienti, filtrati su filtri Whatman® GF/F (porosità nominale = 0,5 µm), sono stati analizzati in laboratorio mediante autoanalizzatore Systea® a flusso continuo segmentato, utilizzando le metodiche riportate in Strickland e Parsons (1968) e Hansen e Koroleff (1999) relativamente ad ammoniaca, nitriti, nitrati ed ortosilicati; gli ortofosfati sono stati determinati manualmente con metodo spettrofotometrico, come indicato in Strickland e Parsons (1968); i filtri per la stima della clorofilla *a* (Whatman GF/F®) sono stati estratti in acetone al 90% ed analizzati secondo il metodo fluorimetrico (Holm-Hansen et al., 1965) mediante luminometro Perkin-Elmer® LS-5B.

I campioni per la stima delle abbondanze fitoplanctoniche, raccolti mediante bottiglie Niskin alle quote summenzionate, sono stati fissati con formaldeide tamponata con esametilentetramina e posti in bottiglie di vetro scuro da 250 ml; i conteggi di abbondanza ed il riconoscimento tassonomico sono stati effettuati secondo Utermöhl (1958) su camere di sedimentazione a volume variabile tra 2 e 50 ml.

Gli organismi mesozooplanctonici sono stati raccolti lungo la colonna d'acqua con pescata obliqua mediante un campionatore a strascico orizzontale tipo Apstein (diametro di bocca = 40 cm) fornito di retino di nylon con vuoto di maglia di 200 µm e di flussometro (Zunini Sertorio, 1990), e fissati con formaldeide al 40% neutralizzata con tetraborato di sodio; l'identificazione ed il conteggio delle abbondanze è stato eseguito allo stereomicroscopio su subcampioni statisticamente rappresentativi, ottenuti mediante un sezionatore tipo Folsom (McEven *et al.*, 1954).

L'ittioplancton è stato campionato con retino FAO (diametro = 100 cm), dotato di maglia da 500 µm, di flussometro TSK® e di depressore idrodinamico del peso di circa 15 kg, opportunamente sagomato, con pescate oblique, da circa 4 m dal fondo fino alla superficie, per una durata di circa 20' (Chicharo *et al.*, 2003). Gli organismi raccolti sono stati fissati con formalina al 4% tamponata con tetraborato di sodio e conteggiati con stereomicroscopio con ingrandimenti da 8x a 40x e con stereomicroscopio con ingrandimenti da 6x e 100x collegato ad un sistema di analisi d'immagine.

## 2. Stima della variabilità dell'idrologia e del campo di corrente a breve scala temporale.

Per le registrazioni continue, al fondo della tagna MR08 (m 22) è stato fissato un correntometro Valeport® 116 (sostituito, per circa 5 mesi, causa manutenzione, da un analogo strumento AAndera®) ed una sonda multiparametrica Hydrolab® DataSonde 4 (vedi schema), attivati in modalità autoregistrante. Il primo strumento acquisiva dati orari relativamente a pressione, temperatura, direzione e velocità del flusso (il correntometro AAndera® non era equipaggiato con sensore di temperatura), mentre la sonda Hydrolab® registrava temperatura, salinità, ossigeno disciolto e pH, con una frequenza di acquisizione compresa tra 20' e 1 h. La gestione degli strumenti (posizionamento, recupero, scarico dati, manutenzione, calibrazione, riprogrammazione e nuovo posizionamento) avveniva in loco, mediante immersione subacquea. La graficazione e la mappatura dei dati sono state ottenute con software commerciale (Grafer® e Surfer® [www.goldensoftware.com](http://www.goldensoftware.com)).

*Schema dell'ancoraggio della strumentazione autoregistrante, posta al fondo della tagna MR08 (m 22).*

Vengono riportati, per confronto, alcuni dati del campo di corrente registrato sulla tagnù P204.

### **Risultati.**

I risultati del Progetto, illustrati sotto forma di tabelle, grafici e mappe tematiche, seguono il seguente schema:

1. variabilità stagionale:

distribuzione verticale dell'idrologia da campagne oceanografiche condotte sulle 8 tagnùe;

2. campo di corrente e idrologia a breve scala temporale:

registrazioni in continuo al fondo della tagnù MR08 (m. 22);

3. portate del fiume Po:

portate del Po negli anni dei campionamenti (2006, 2007, 2008);

4. galleria fotografica.

### **Ringraziamenti.**

Si ringraziano i sigg. Mauro Penzo (CNR-ISMAR, conduttore dell'imbarcazione "Boreana") e Marco Costantini (Associazione "Tegnùe di Chioggia - Onlus", proprietario e conduttore dell'imbarcazione "Falco II"): senza il loro prezioso aiuto, durante le campagne di campionamento e nelle attività in immersione, questo lavoro non sarebbe stato possibile; il sig. Piero Mescalchin, presidente dell'Associazione "Tegnùe di Chioggia - Onlus" per la collaborazione prestata; la dr.ssa Carlotta Mazzoldi, la dr.ssa Tihana Marčeta, la dr.ssa Eleonora Scalco e numerosi studenti del Dipartimento di Biologia dell'Università di Padova per la fattiva collaborazione nelle operazioni in mare; il dr. Alfredo Boldrin (CNR-ISMAR) per il processamento dei dati di corrente acquisiti dal correntometro AAndera® e per aver fornito i dati di portata del fiume Po; il dr. Gianluca Franceschini (I.S.P.R.A. Chioggia) per aver gentilmente fornito i dati di corrente della tagnù P204; la CORR-TEK Idrometria srl di Verona ([www.ott.com/it-it/](http://www.ott.com/it-it/)) per l'assistenza strumentale.

### **Finanziamento.**

Questo studio preliminare è stato interamente finanziato dal CNR-ISMAR di Venezia (<http://www.ismar.cnr.it/>), con il supporto logistico, per le registrazioni strumentali sulla tagnù MR08, dell'Associazione "Tegnùe di Chioggia - Onlus".

# **1. VARIABILITÀ STAGIONALE DELL'IDROLOGIA**

Grafici e mappe relative ai parametri oceanografici acquisiti nel corso delle campagne di misura e campionamento sulle 8 tegnùe oggetto di studio, per il periodo febbraio 2006 – dicembre 2007.

## **1.1. Profili verticali**

Profili verticali da sonda multiparametrica per campagne di misura.

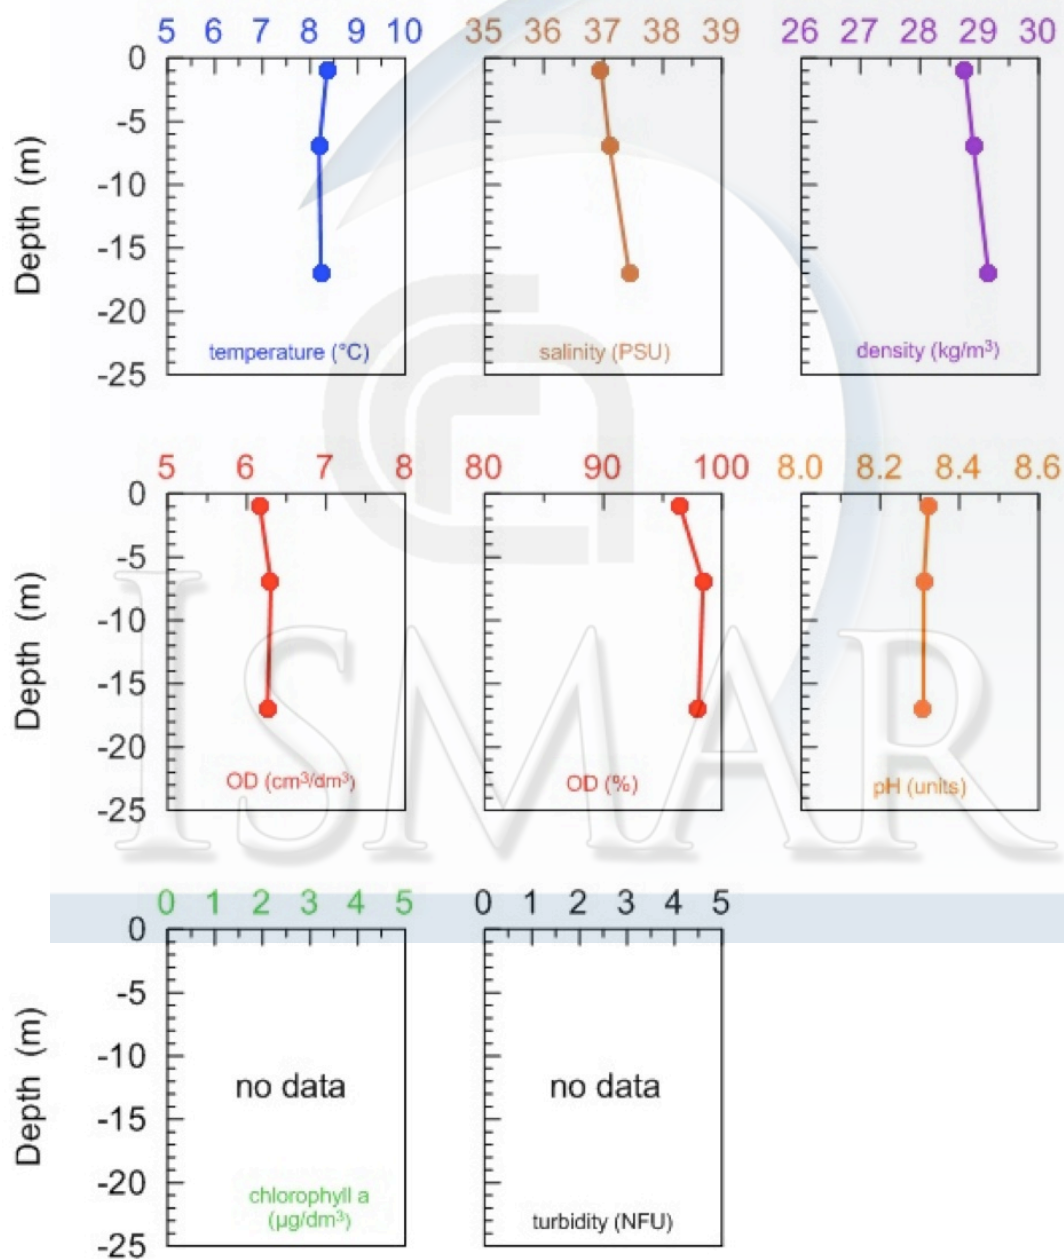

Per la tegnùà TDA (PINTE\_00\_02) i profili idrologici sono ottenuti da bottiglie Niskin (CTD in avaria).

### 1.3. Transetto costa-largo

La mappa mostra, in giallo, la sezione considerata (Chioggia > P204 > AL > MR08 > TQS > TSO) come transetto costa-largo, lungo circa 20 miglia nautiche. Le figure illustrano le distribuzioni verticali di temperatura, salinità, anomalia di densità, ossigenazione relativa, torbidità e clorofilla *a*, da sonda multiparametrica, lungo questo transetto.

Gli istogrammi bianchi sovrainposti sulla sezione di salinità rappresentano la profondità di scomparsa del disco di Secchi, indice di trasparenza delle acque.

## **2.1. CORRENTOMETRIA MR08**

### ***2.1.1. Diagramma a rosa per l'intero periodo di studio***

Diagramma a rosa della direzione della corrente al fondo della tagnù MR08, ottenuto dai dati acquisiti durante il periodo di studio (27/06/2006 > 20/11/2008).

È evidente la direzione prevalente verso sud (170°-180°).

### ***2.1.2. Diagrammi a rosa: direzione della corrente tra le tegnùe MR08 e P204***

Confronto della direzione della corrente tra le  
tegnùe MR08 e P204.

Sebbene i periodi differiscano (anni e intervalli  
temporali diversi), è evidente la direzione della  
corrente lungo l'asse nord-sud per entrambe le aree,  
con prevalenza verso sud a causa della circolazione  
ciclonica del bacino nord-adriatico.

### ***2.1.3. Velocità della corrente***

Vettori di velocità della corrente al fondo, ripartiti per mesi.

I segmenti sono orientati secondo la direzione di flusso della corrente, con una lunghezza proporzionale alla sua velocità.

Il valore massimo di velocità (= 43,8 cm/s) è stato misurato l'11 settembre 2007.

## **2.2. IDROLOGIA MR08**

### ***2.2.1. Temperatura e pressione***

Registrazioni di temperatura (da correntometro e da sonda) e di pressione (da correntometro) al fondo della tagnù MR08, ripartite per anni di campionamento (2006, 2007, 2008) ed ordinate per mese. Gli andamenti della pressione sono equiparabili, con notevole approssimazione, alle curve di marea. Il differente livello dei sensori (sensore T correntometro = m 20,5; sensore T sonda = m 22) evidenzia fenomeni di “microstratificazione” termica presente in prossimità del fondo.

In alto sono indicate le fasi lunari.

### 3. PORTATE DEL FIUME PO

Portate giornaliere del fiume Po negli anni considerati dalla presente ricerca (tratto rosso).

Gli istogrammi indicano le medie mensili dei dati storici (periodo dal 1918 al 2005); la portata media dal 1918 al 2005 è pari a  $\text{m}^3/\text{s}$  1483.

ISMAR

ISMAR

Franco Bianchi. Progetto INtegrato TEGnùe. (PINTE). *Idrologia delle Tegnùe di Chioggia (Adriatico Settentrionale, Italia).*  
*Studio Preliminare (anni 2006, 2007, 2008).*

La m/b “*Boreana*” dell’ISMAR CNR di Venezia, utilizzata per l’esecuzione delle campagne oceanografiche.

Alcune tagnùe sono segnalate da boe posizionate dall’*Associazione Tagnùe di Chioggia*” Onlus.

Strumentazione di misura e campionamento a bordo della m/b “Boreana”.

Viene calata la sonda multiparametrica per indagare la struttura verticale della colonna d'acqua.

Per i prelievi a quote discrete vengono utilizzate le bottiglie Niskin.

Retini per il campionamento dello zooplancton (in preparazione) e dell'ittioplancton (in basso).

La m/b “*Falco II*” del sig. Marco Costantini, messa a disposizione dall’ “*Associazione Tegnùe di Chioggia*” Onlus per lo studio al fondo della tegnùe MR08.

Preparazione e calibrazione della sonda multiparametrica a bordo.

Mediante immersione subacquea, la strumentazione autoregistrante viene collocata al fondo della tagnù MR08.

Ancoraggio al fondo del correntometro e della sonda (m 22).

Dopo circa un mese...

...si procede al recupero degli strumenti.
